Recursion

Recursion

- A process by which a function calls itself repeatedly
 - □ Either directly.
 - X calls X
 - ☐ Or cyclically in a chain.
 - X calls Y, and Y calls X
- Used for repetitive computations in which each action is stated in terms of a previous result fact(n) = n * fact (n-1)

Contd.

- For a problem to be written in recursive form, two conditions are to be satisfied:
 - It should be possible to express the problem in recursive form
 - Solution of the problem in terms of solution of the same problem on smaller sized data
 - The problem statement must include a stopping condition

fact(n) = 1, if
$$n = 0$$
= $n * fact(n-1)$, if $n > 0$
Recursive definition

Examples:

□ Factorial: fact(0) = 1fact(n) = n * fact(n-1), if n > 0□ GCD: gcd(m, m) = mgcd(m, n) = gcd(m%n, n), if m > ngcd(m, n) = gcd(n, n%m), if m < n□ Fibonacci series (1,1,2,3,5,8,13,21,....) fib(0) = 1fib(1) = 1fib (n) = fib (n-1) + fib (n-2), if n > 1

Factorial

```
long int fact (int n)
  if (n == 1)
     return (1);
  else
     return (n * fact(n-1));
```

```
long int fact (int n)
{
    if (n = = 1) return (1);
    else return (n * fact(n-1));
}
```

```
fact(4)
```

```
long int fact (int n)
{
    if (n = = 1) return (1);
    else return (n * fact(n-1));
}
```

```
long int fact (int n)
{
    if (n = = 1) return (1);
    else return (n * fact(n-1));
}
```

```
fact(4)

if (4 = = 1) return (1);
else return (4 * fact(3));

if (3 = = 1) return (1);
else return (3 * fact(2));

↓
```

```
long int fact (int n)
{
    if (n = = 1) return (1);
    else return (n * fact(n-1));
}
```

```
fact(4)
      if (4 = = 1) return (1);
      else return (4 * fact(3));
                        if (3 = 1) return (1);
                        else return (3 * fact(2));
                                         if (2 = = 1) return (1);
                                         else return (2 * fact(1));
long int fact (int n)
   if (n = 1) return (1);
  else return (n * fact(n-1));
```

```
fact(4)
      if (4 = = 1) return (1);
      else return (4 * fact(3));
                        if (3 = 1) return (1);
                        else return (3 * fact(2));
                                         if (2 = = 1) return (1);
                                         else return (2 * fact(1));
long int fact (int n)
                                                       if (1 = = 1) return (1);
   if (n = 1) return (1);
  else return (n * fact(n-1));
```

```
fact(4)
      if (4 = = 1) return (1);
      else return (4 * fact(3));

                                         if (2 = = 1) return (1);
                                         else return (2 * fact(1));
long int fact (int n)
                                                      if (1 = = 1) return (1);
  if (n = 1) return (1);
  else return (n * fact(n-1));
```

Look at the variable addresses (a slightly different program)!

```
int main()
  int x,y;
  scanf("%d",&x);
  y = fact(x);
  printf ("M: x = %d, y = %d\n", x,y);
  return 0;
int fact(int data)
{ int val = 1;
 printf("F: data = \%d, &data = \%u \n
  &val = \%u\n'', data, &data, &val);
 if (data>1) val = data*fact(data-1);
  return val;
```

Output

```
F: data = 4, & data = 3221224528
&val = 3221224516
F: data = 3, & data = 3221224480
&val = 3221224468
F: data = 2, & data = 3221224432
&val = 3221224420
F: data = 1, & data = 3221224384
&val = 3221224372
M: x=4, y=24
```

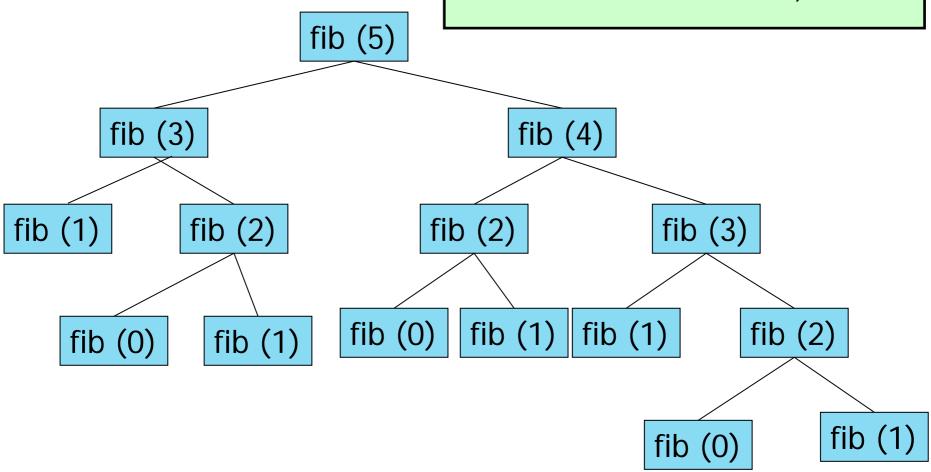

Fibonacci Numbers

```
Fibonacci recurrence:
fib(n) = 1 if n = 0 or 1;
= fib(n - 2) + fib(n - 1)
otherwise;
```

```
int fib (int n) {
   if (n == 0 || n == 1)
      return 1;
   return fib(n-2) + fib(n-1);
}
```

Fibonacci recurrence:

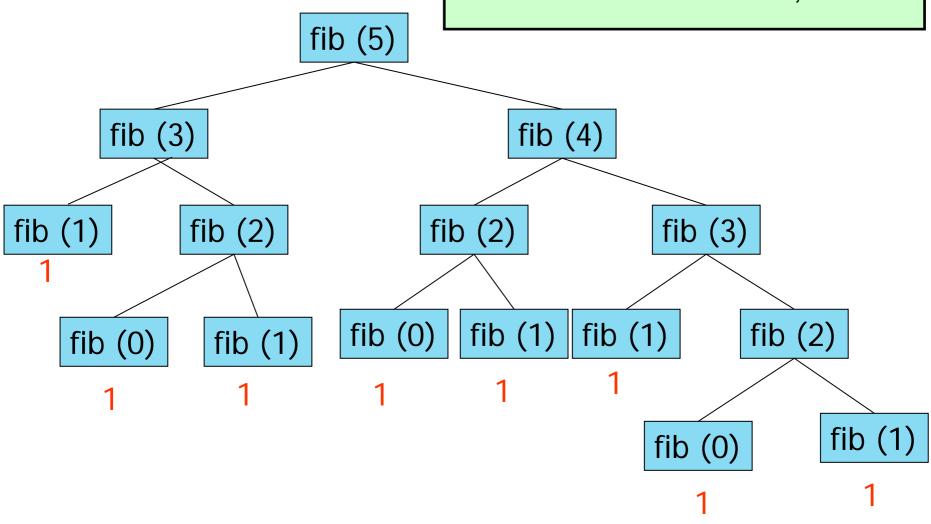

$$fib(n) = 1$$
 if $n = 0$ or 1;
= $fib(n-2) + fib(n-1)$
otherwise;

```
int fib (int n) {
   if (n == 0 || n == 1)
      return 1;
   return fib(n-2) + fib(n-1);
}
```

Fibonacci recurrence:

$$fib(n) = 1$$
 if $n = 0$ or 1;
= $fib(n-2) + fib(n-1)$
otherwise;

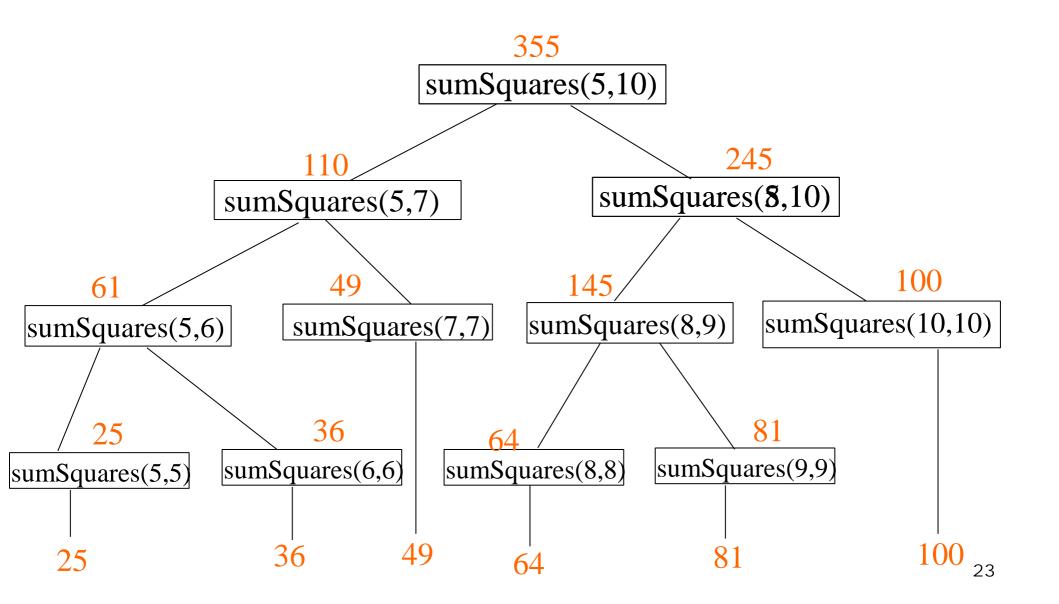

```
int fib (int n) {
                                        Fibonacci recurrence:
  if (n==0 | | n==1)
        return 1;
                                        fib(n) = 1 \text{ if } n = 0 \text{ or } 1;
  return fib(n-2) + fib(n-1);
                                                 = fib(n-2) + fib(n-1)
                                                         otherwise;
                            fib (5)
              3
                                             fib (4)
           fib (3)
                                                         fib (3)
                  fib (2)
                                      fib (2)
   fib (1)
                                         fib (1)
                                                  fib (1)
                                                                 fib (2)
                               fib (0)
        fib (0)
                    fib (1)
                                                                       fib (1)
                                                         fib (0)
```

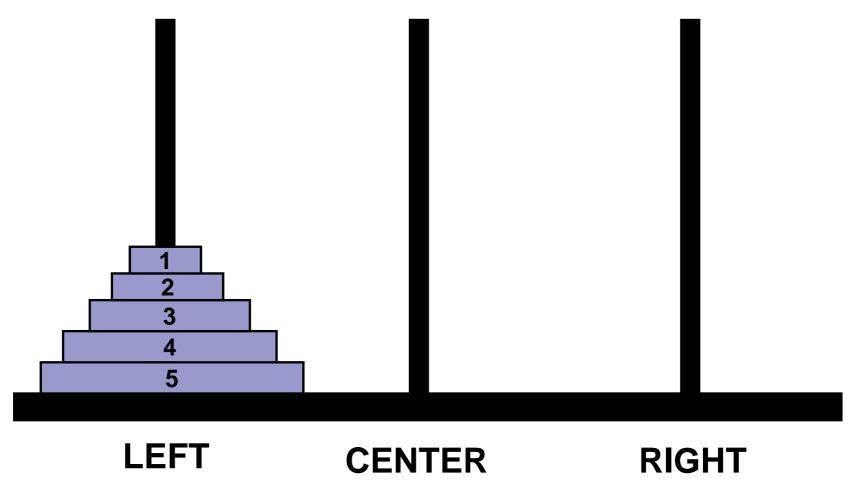

Sum of Squares

```
int sumSquares (int m, int n)
   int middle;
   if (m == n) return m*m;
   else
      middle = (m+n)/2;
      return sumSquares(m,middle)
                + sumSquares(middle+1,n);
```

Annotated Call Tree

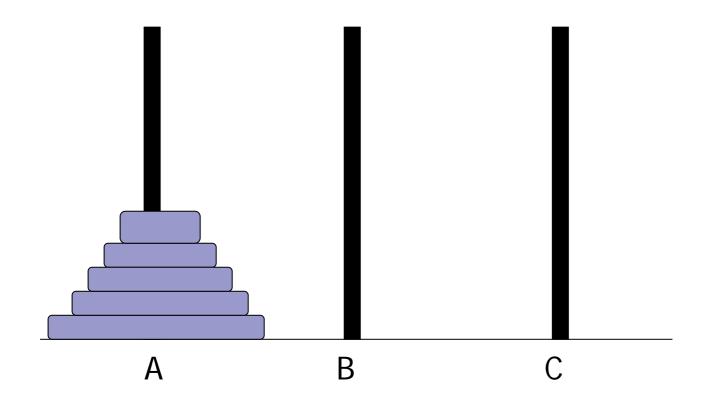

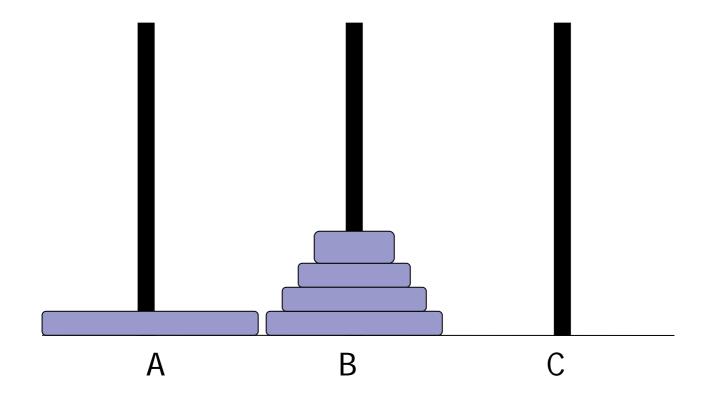

Towers of Hanoi Problem

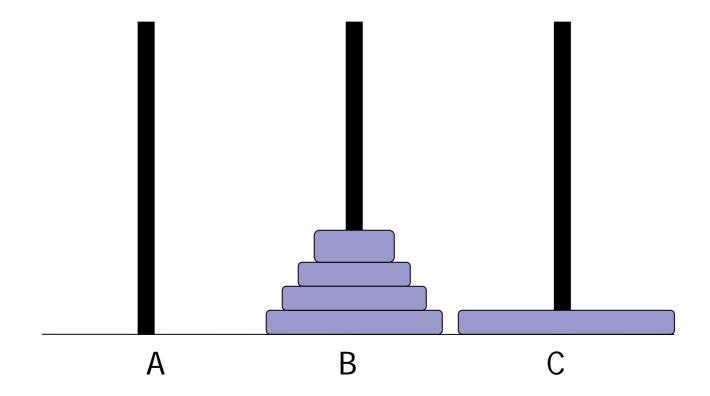

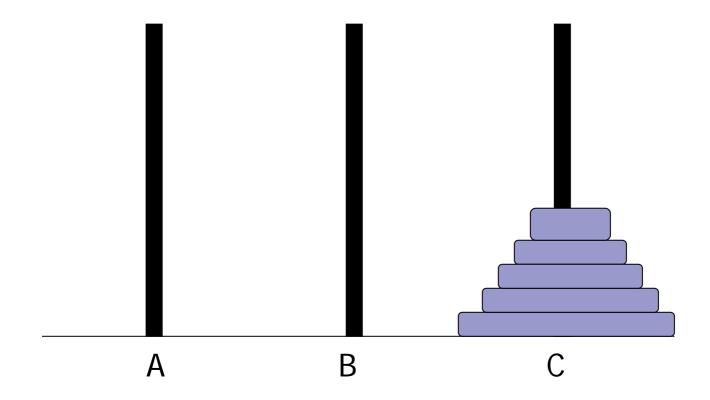

- Initially all the disks are stacked on the LEFT pole
- Required to transfer all the disks to the RIGHT pole
 - □ Only one disk can be moved at a time.
 - A larger disk cannot be placed on a smaller disk
- CENTER pole is used for temporary storage of disks

- Recursive statement of the general problem of n disks
 - ☐ Step 1:
 - Move the top (n-1) disks from LEFT to CENTER
 - □ Step 2:
 - Move the largest disk from LEFT to RIGHT
 - □ Step 3:
 - Move the (n-1) disks from CENTER to RIGHT

Towers of Hanoi function

```
void towers (int n, char from, char to, char aux)
/* Base Condition */
if (n==1)
       printf ("Disk 1: %c \rightarrow &c \n", from, to);
       return;
   /* Recursive Condition */
      towers (n-1, from, aux, to);
```

Towers of Hanoi function

```
void towers (int n, char from, char to, char aux)
/* Base Condition */
if (n==1) {
        printf ("Disk 1: %c \rightarrow &c \n", from, to);
        return;
   /* Recursive Condition */
      towers (n-1, from, aux, to);
      printf ("Disk %d: %c \rightarrow %c\n", n, from, to);
```

Towers of Hanoi function

```
void towers (int n, char from, char to, char aux)
/* Base Condition */
if (n==1)
       printf ("Disk 1: %c \rightarrow %c \n", from, to);
        return;
   /* Recursive Condition */
      towers (n-1, from, aux, to);
      printf ("Disk %d: %c \rightarrow %c\n", n, from, to);
      towers (n-1, aux, to, from);
```

TOH runs

```
void towers(int n, char from, char to, char aux)
\{ if (n==1) \}
{ printf ("Disk 1 : %c \rightarrow %c \n", from, to);
                                                     3
  return;
 towers (n-1, from, aux, to);
 printf ("Disk %d: %c -> %c\n", n, from, to);
 towers (n-1, aux, to, from);
int main()
{ int n;
 scanf("%d", &n);
 towers(n,'A','C','B');
 return 0;
```

Output

```
3
Disk 1: A -> C
Disk 2: A -> B
Disk 1: C -> B
Disk 3: A -> C
Disk 1: B -> A
Disk 2: B -> C
Disk 1: A -> C
```

More TOH runs

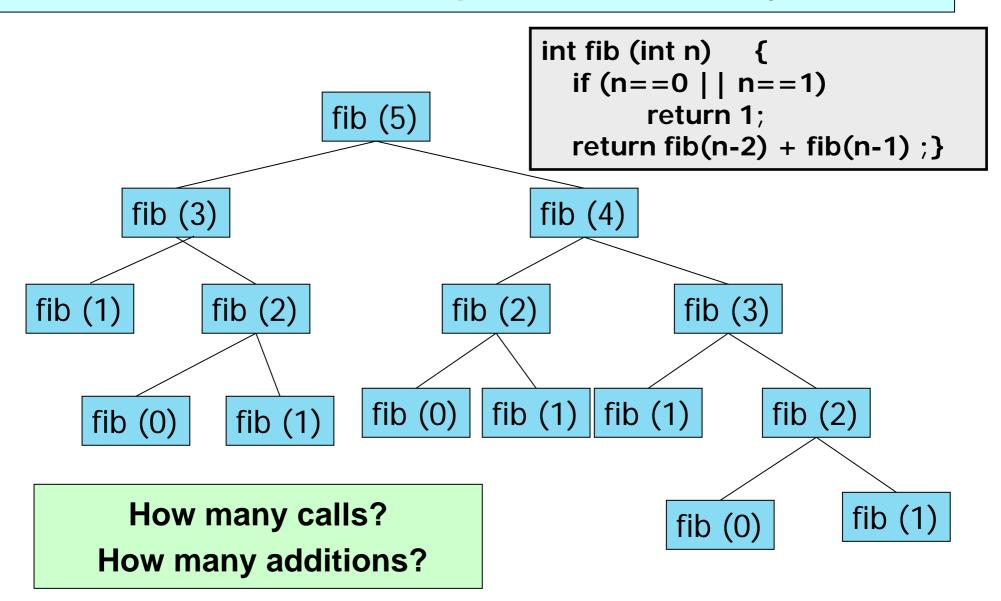

```
void towers(int n, char from, char to, char aux)
{ if (n==1)
{ printf ("Disk 1 : %c \rightarrow %c \n", from, to);
  return;
 towers (n-1, from, aux, to);
 printf ("Disk %d: %c -> %c\n", n, from, to);
 towers (n-1, aux, to, from);
int main()
{ int n;
 scanf("%d", &n);
 towers(n,'A','C','B');
 return 0;
```

Output

Disk $1:A \rightarrow B$ Disk $2:A \rightarrow C$ Disk $1:B \rightarrow C$ Disk $3:A \rightarrow B$ Disk $1:C\rightarrow A$ Disk 2: C -> B Disk $1:A \rightarrow B$ Disk $4:A \rightarrow C$ Disk $1:B \rightarrow C$ Disk $2: B \rightarrow A$ Disk $1:C\rightarrow A$ Disk $3:B \rightarrow C$ Disk $1 : A \rightarrow B$ Disk $2:A \rightarrow C$ Disk $1:B \rightarrow C$

Relook at recursive Fibonacci:

Not efficient !! Same sub-problem solved many times.

Iterative Fib

```
int fib( int n)
{ int i=2, res=1, m1=1, m2=1;
 if (n == 0 || n == 1) return res;
 for (; i<=n; i++)
 { res = m1 + m2;}
  m2 = m1;
  m1 = res;
 return res;
int main()
{ int n;
 scanf("%d", &n);
 printf(" Fib(%d) = %d \n", n, fib(n));
 return 0;
```

Much Less Computation here! (How many additions?)

An efficient recursive Fib

```
int Fib(int m1, int m2, int n, int i)
int Fib (int, int, int, int);
                                          int res;
                                          if (n == i)
int main()
                                            res = m1 + m2;
                                          else
 int n;
                                            res = Fib(m1+m2, m1, n, i+1);
 scanf("%d", &n);
                                          return res;
 if (n == 0 || n == 1)
  printf("F(%d) = %d \n", n, 1);
 else
  printf("F(\%d) = \%d \n", n, Fib(1,1,n,2));
 return 0;
                              Much Less Computation here!
                                (How many calls/additions?)
```

Run

Output

```
$ ./a.out
int Fib (int, int, int, int);
int main()
{ int n;
                                                        F: m1=1, m2=1, n=3, i=2
 scanf("%d", &n);
                                                        F: m1=2, m2=1, n=3, i=3
 if (n == 0 || n == 1) printf("F(%d) = %d \n", n, 1);
 else printf("F(\%d) = \%d \ n", n, Fib(1,1,n,2));
                                                        F(3) = 3
 return 0;
int Fib(int m1, int m2, int n, int i)
                                                        $ ./a.out
{ int res;
                                                        5
 printf("F: m1=\%d, m2=\%d, n=\%d, i=\%d\n",
                        m1, m2, n, i);
                                                        F: m1=1, m2=1, n=5, i=2
if (n == i)
                                                        F: m1=2, m2=1, n=5, i=3
  res = m1 + m2;
                                                        F: m1=3, m2=2, n=5, i=4
 else
   res = Fib(m1+m2, m1, n, i+1);
                                                        F: m1=5, m2=3, n=5, i=5
return res;
                                                        \mathbf{F(5)} = \mathbf{8}
```

Static Variables

```
int Fib (int, int);
int main()
  int n;
  scanf("%d", &n);
  if (n == 0 || n == 1)
    printf("F(\%d) = \%d \n", n, 1);
  else
    printf("F(\%d) = \%d \n", n,
  Fib(n,2));
  return 0;
```

```
int Fib(int n, int i)
  static int m1, m2;
  int res, temp;
  if (i==2) {m1 =1; m2=1;}
  if (n == i) res = m1 + m2;
  else
    temp = m1;
     m1 = m1 + m2;
     m2 = temp;
     res = Fib(n, i+1);
  return res;
```

Static variables remain in existence rather than coming and going each time a function is activated

Static Variables: See the addresses!

```
int Fib(int n, int i)
 static int m1, m2;
 int res, temp;
 if (i==2) {m1 =1; m2=1;}
 printf("F: m1=%d, m2=%d, n=%d,
             i=%d\n'', m1,m2,n,i);
 printf("F: &m1=%u, &m2=%u\n",
                    &m1,&m2);
 printf("F: &res=%u, &temp=%u\n",
               &res,&temp);
 if (n == i) res = m1 + m2;
 else { temp = m1; m1 = m1+m2;
    m2 = temp;
    res = Fib(n, i+1); 
 return res;
```

Output

```
F: m1=1, m2=1, n=5, i=2
F: &m1=134518656, &m2=134518660

Recursion vs. Iteration

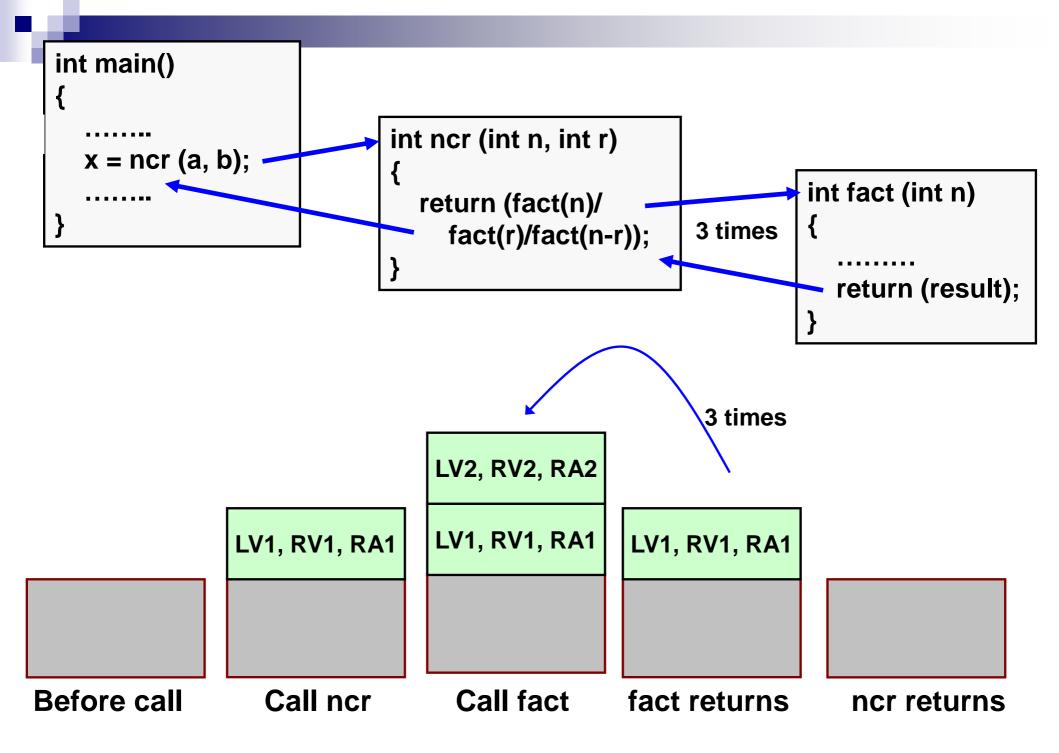

- Repetition
 - □ Iteration: explicit loop
 - □ Recursion: repeated function calls
- Termination
 - Iteration: loop condition fails
 - □ Recursion: base case recognized
- Both can have infinite loops
- Balance
 - Choice between performance (iteration) and good software engineering (recursion).

- Every recursive program can also be written without recursion
- Recursion is used for programming convenience, not for performance enhancement
- Sometimes, if the function being computed has a nice recurrence form, then a recursive code may be more readable

How are function calls implemented?

- The following applies in general, with minor variations that are implementation dependent
 - □ The system maintains a stack in memory
 - Stack is a last-in first-out structure
 - Two operations on stack, push and pop
 - Whenever there is a function call, the activation record gets pushed into the stack
 - Activation record consists of the return address in the calling program, the return value from the function, and the local variables inside the function

```
int main()
                                                  int gcd (int x, int y)
           x = gcd(a, b);
                                                    return (result);
                                    Local
                Activation
                                   Variables
                record
                                 Return Value
STACK
                                 Return Addr
                                                        After return
            Before call
                                  After call
```

What happens for recursive calls?

- What we have seen
 - Activation record gets pushed into the stack when a function call is made
 - □ Activation record is popped off the stack when the function returns
- In recursion, a function calls itself
 - Several function calls going on, with none of the function calls returning back
 - Activation records are pushed onto the stack continuously
 - Large stack space required

Activation records keep popping off, when the termination condition of recursion is reached

- We shall illustrate the process by an example of computing factorial
 - ☐ Activation record looks like:

Local Variables Return Value Return Addr

Example:: main() calls fact(3)

```
int main()
{
  int n;
  n = 3;
  printf ("%d \n", fact(n));
  return 0;
}
```

```
int fact (int n)
{
    if (n = = 0)
       return (1);
    else
      return (n * fact(n-1));
}
```

TRACE OF THE STACK DURING EXECUTION

main calls fact

> RA .. fact n = 3n = 3

n = 2

RA.. main RA.. main RA.. main RA.. main RA.. main RA.. main RA.. main

n = 1

RA.. fact

n = 2

RA .. fact

n = 3

n = 0

RA.. fact

n = 1

RA.. fact

n = 2

RA.. fact

n = 3

n = 1

1*1 = 1

RA.. fact

n = 2

RA .. fact

n = 3

to main

n = 2

2*1 = 2

RA.. fact

n = 3

fact returns

n = 3

3*2 = 6

Do Yourself

 Trace the activation records for the following version of Fibonacci sequence

```
int f (int n)
              int a, b;
              if (n < 2) return (n);
              else {
               a = f(n-1);
            \rightarrow b = f(n-2);
             → return (a+b);
          void main() {
             printf("Fib(4) is: %d \n", f(4));
main
```

```
Local
Variables
(n, a, b)

Return Value
Return Addr
(either main,
or X, or Y)
```
